

TITLE OF THE INVENTION
"TERMINAL FOR COMPUTER NETWORK AND
RECORDING METHOD OF CONTROL HISTORY"

5 BACKGROUND OF THE INVENTION

(1) Field of the Invention

The present invention relates to a terminal for a computer network and a method of recording control operation history data, and more particularly to a
10 technique of recording remote control operation history data in a computer network in which one of a plurality of terminals connected through the network is used as a control terminal for conducting remote control operation of another terminal on a screen
15 sharing basis.

(2) Description of the Related Art

In Japanese Unexamined Patent Publication No. H8 (1996) - 235093 and No. H3 (1991) - 276342, for example, it has been proposed to provide a remote control type
20 computer network system, comprising a plurality of terminals or computers, in which one of the terminals (control terminal) conducts remote operation of another terminal (remote controlled terminal) on a screen sharing basis.

25 In the remote control type computer network system,

an input operation by an operator at the control terminal is transferred to the remote controlled terminal, and in response to the input operation, an application program is executed on the remote
5 controlled terminal. When the contents displayed on a screen at the remote controlled terminal are changed as a result of execution of the application program, the contents thus changed are reflected to the control terminal. In this manner, the operator at the control
10 terminal can carry out remote operation while viewing displayed contents identical to those at the remote controlled terminal.

As an operation history recording method in the remote control type computer network system mentioned
15 above, there is a conventional technique in which remote control operation history information indicating the transition of displayed contents due to the operator's input operations is stored at the control terminal and a sequence of operations is reproduced at the control
20 terminal as required, for example.

However, in this operation history recording method in which operation history data is stored at the control terminal, a user at the remote controlled terminal cannot check immediately whether the remote
25 controlled terminal has been operated by another person

and what operation has been performed during the absence of the user.

Further, according to the above-mentioned operation history recording method of storing
5 operation history data at a control terminal, for example, when a system administrator carries out maintenance of a multiplicity of networked user terminals through remote operations in an intra-company information system, a huge amount of
10 operation history data is stored in the terminal of the system administrator. This causes difficulty in storage and reference of the operation history data.

In a distributed processing type network in which data stored in a file server is accessed by a plurality
15 of terminals, operation history data from each terminal is recorded into the file server on the remote controlled side. In this case, the operation history data is stored in the file server for such a purpose as troubleshooting. For example, as disclosed in
20 Japanese Unexamined Patent Publication No. H6 (1994) - 67956, operation history data indicating which terminal has performed what operation in which file region is recorded.

It is therefore an object of the present invention to provide a computer network terminal which works as a remote controlled terminal allowing a user to check remote control operation history data thereof with
5 ease.

Another object of the present invention is to provide an operation history recording method which is applicable to a computer network, particularly to a remote control network system of a screen sharing
10 type, for allowing a user at a remote controlled terminal to check remote operation history data thereof with ease.

A further object of the present invention is to provide an operation history recording method,
15 applicable to a computer network, which can reduce the amount of remote operation history data at a control terminal by storing the history data in a distributed fashion.

In the present invention, for solving the
20 above-mentioned problems, a remote controlled terminal is provided with a function for recording remote control operation history data so that a change in the displayed contents due to remote control can be reproduced easily.

25 More specifically, according to one aspect of the

present invention, a terminal comprises means for receiving a remote operation message from a distant terminal through a network, input means for entering remote operation input information extracted from the
5 received message into an operating system, and history recording means for recording the remote operation input information and transition of a terminal screen in response to the remote operation as remote operation history data.

- 10 Further, according to another aspect of the present invention, the terminal is provided with: communication control means for receiving remote operation input information from a distant terminal through a network, remote operation basic control means
15 for entering the received remote operation input information into an operating system, and history recording means for creating a remote operation history file according to the remote operation input information and information supplied from the
20 operating system to an application program and a display controller.

Still further, according to another aspect of the present invention, the history recording means automatically starts remote control operation history
25 recording when remote operation input information from

the distant terminal or terminal operations carried out in response to the remote operation input information satisfy a predetermined start condition.

Furthermore, according to another aspect of the present invention, the history recording means automatically stops remote operation history recording when remote operation input information from the distant terminal or terminal operations carried out in response to the remote operation input information satisfy a predetermined stop condition. The remote operation history recording may be automatically stopped after a lapse of a predetermined time period from the start of remote operation history recording.

According to the present invention, there is provided a remote operation history recording method for use in a computer network system in which one of a plurality of networked terminals is used as a control terminal for conducting remote operation of another terminal, comprising the steps of: (1) sending a remote operation message from the control terminal to a remote controlled terminal; (2) extracting remote operation input information from the remote operation message received by the remote controlled terminal, and executing a program operation at the remote controlled

terminal according to the extracted remote operation input information; (3) storing, as operation history data, event information generated at the remote controlled terminal according to the remote operation

5 input information; (4) sending a message indicating the results of execution of the program operation from the remote controlled terminal to the control terminal; and (5) storing, as operation history data, event information indicating the results of execution of the

10 program operation at the remote controlled terminal.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram showing a basic configuration of a remote control type computer network system to

15 which the present invention is applicable.

FIG. 2 is a diagram showing system configurations of a remote controlled terminal 100A and a control terminal 100B.

FIG. 3 is a diagram showing the transfer flow of

20 remote operation input from the control terminal 100B to the remote controlled terminal 100A.

FIG. 4 is a diagram showing a message format for keyboard data to be sent from the control terminal 100B.

FIG. 5 is a diagram showing a message format for

25 mouse data to be sent from the control terminal 100B.

FIG. 6 is a diagram showing a flow of operation in execution of an application program on the remote controlled terminal 100A.

FIG. 7 is a diagram showing a message format for
5 screen drawing data to be sent from the remote controlled terminal 100A to the control terminal 100B.

FIG. 8 is a diagram showing operation history recording at the remote controlled terminal 100A.

FIG. 9 is a diagram showing an example of a remote
10 operation history file.

FIG. 10 is a flowchart showing the function of an operation recording and playing controller 25A.

FIGS. 11A to 11D show exemplary recording start events tables 60.

FIGS. 12A to 12D show exemplary recording
15 termination events tables 70.

FIG. 13 is a diagram showing a table counter 81 and an event counter 82 used by the operation recording and playing controller 25A.

FIG. 14 is a flowchart showing details of a process
20 100 for judgment on conditions of recording start.

FIG. 15 is a flowchart showing details of a parameter initialization process 120 to initialize parameters for judgment on termination of recording.

FIG. 16 is a flowchart showing details of a process
25

130 for the judgment on conditions of recording termination.

FIG. 17 is a flowchart showing details of an event recording process 140.

5 FIG. 18 is a diagram for explaining operation history playing control.

FIG. 19 is a flowchart of operation history playing control 150.

10 FIG. 20 is a diagram showing an example of a graphical user interface window for operation history playing control.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

15 The embodiments of the present invention will now be described in detail with reference to the accompanying drawings.

Referring to FIG. 1, there is shown a basic configuration of a remote control type computer network system to which the present invention is applicable.

20 This computer network system is comprised of a plurality of computers or terminals interconnected through a communication network 200. For the sake of simplicity, FIG. 1 shows just two terminals 100A and 100B working as a remote controlled terminal and a
25 control terminal respectively. Each of these

terminals comprises a display 2 (2A, 2B), a keyboard 3 (3A, 3B), a mouse 4 (4A, 4B), and a processor 1 (1A, 1B) equipped with a communication interface.

Each of the terminals 100A and 100B may be a
 5 general-purpose personal computer or a dedicated terminal having special functions such as a workstation. Further, as the communication network 200, a LAN (Local Area Network) may be employed in a company, or a public switched telephone network or an ISDN (Integrated
 10 Services Digital Network) may be employed in a case where terminals to be connected are located in a wide area.

In an intra-company information system, a multiplicity of terminals located at respective
 15 sections are interconnected through a communication network, and a system administrator belonging to an information system section carries out remote control for high-level operation tasks which are difficult for general terminal users, such as changing a table
 20 parameter or code in a specific application, acquiring and analyzing a faulty situation on occurrence of a trouble, and recovering from a trouble.

In the following description, the terminal 100A is treated as a remote controlled terminal (agent
 25 terminal) and the terminal 100B is treated as a control

terminal (controller terminal). In a practical application, a single terminal may conduct remote control of a plurality of terminals, or contrarily a single terminal may be remote-controlled from a plurality of terminals. Further, in a modified arrangement, remote operation may be conducted in series in a plurality of remote controlled terminals by connecting one remote controlled terminal to another remote controlled terminal.

As shown in FIG. 1, the display 2B of the control terminal 100B presents the same contents as those on the display 2A of the remote controlled terminal 100A. When the operator at the control terminal 100B performs an input operation for a specific window on the display 2B using the keyboard 3B or the mouse 4B, input operation information is sent to the remote controlled terminal 100A through the communication network 200 as indicated by arrow 201. Then, at the remote controlled terminal 100A, the input operation information thus received is handled in the same manner as for input information from the keyboard 3A or the mouse 4A, and the results of execution of an application program on the remote controlled terminal 100A are reflected to the display 2B of the control terminal 100B as indicated by arrow 202.

Referring to FIG. 2, there are shown system configurations of the remote controlled terminal 100A and the control terminal 100B.

The processor 1A of the remote controlled terminal 100A is connected with the display 2A, keyboard 3A, mouse 4A, and such a storage device as a disk controller 5A with a disc storage. The processor 1A is provided with: a display driver 12A for connection with the display 2A, a keyboard driver 13A for connection with the keyboard 3A, a mouse driver 14A for connection with the mouse 4A, and software such as an operating system 10A (OS software), and plural kinds of application programs 11 to be executed under the operating system 10A.

Besides, the processor 1A is provided with the following software for implementing a remote operation function and a remote operation history recording function to be described later: a display driver hooking controller 22A for capturing screen drawing data output from the operating system 10A to the display driver 12A, a keyboard hooking controller 23A for capturing keyboard data input from the keyboard driver 13A to the operating system 10A, a mouse hooking controller 24A for capturing mouse data input from the mouse driver 14A to the operating system 10A, an application hooking

controller 21A for monitoring the controlled state of each of the application programs 11 running under the operating system 10A, an operation recording and playing controller 25A for controlling the writing of operation history data to the disk controller 5A and the reading out of operation history data therefrom, a communication controller 26A for controlling information transfer through the communication network 200, and a remote operation basic controller 20A for presiding over these controllers.

On the other hand, the processor 1B of the control terminal 100B is connected with the display 2B, keyboard 3B, mouse 4B, and such a storage device as a disk controller 5B. In the same fashion as in the remote controlled terminal 100A, the processor 1B is provided with an operating system 10B, a display driver 12B, a keyboard driver 13B, and a mouse driver 14B. Besides, the processor 1B is provided with the following software for implementing a remote operation function and a remote operation history recording function: a keyboard hooking controller 23B, a mouse hooking controller 24B, an operation recording and playing controller 25B, a communication controller 26B, a display controller 27B for outputting screen drawing data received from the remote controlled terminal 100A

on the display 2B, and a remote operation basic controller 20B for presiding over these controllers.

Referring to FIG. 3, there is shown a transfer flow of remote operation input data from the control
 5 terminal 100B to the remote controlled terminal 100A.

In a state that the display 2B of the control terminal 100B presents the same contents (window) as those on the remote controlled terminal 100A, when the operator at the control terminal 100B performs an input
 10 operation for a specific window on the display 2B using the keyboard 3B, the keyboard hooking controller 23B captures input data from the keyboard 3B and passes it to the remote operation basic controller 20B. When the operator performs an input operation using the mouse
 15 4B, the mouse hooking controller 24B captures input data from the mouse 4B and passes it to the remote operation basic controller 20B. Each of these input data is converted into a message having a predetermined format by the remote operation basic controller 20B
 20 and sent out to the communication network 200 via the communication controller 26B. Thus, the message containing the input data is transferred to the remote controlled terminal 100A.

At the remote controlled terminal 100A, the above
 25 message is received by the communication controller

26A and passed to the remote operation basic controller 20A. Then, the remote operation basic controller 20A extracts the input data from the received message and passes the extracted input data to the operating system 10A. Analyzing the extracted input data, the operating system 10A carries out simulation on a corresponding one of the application programs 11A. In the application program 11A, the input data of remote operation is processed in the same manner as for data input from the keyboard 3A or the mouse 4A of the remote controlled terminal 100A.

The data input from the keyboard 3B of the control terminal 100B is transmitted to the remote controlled terminal 100A in a message format, for example, as shown in FIG. 4.

In FIG. 4, reference numeral 301 indicates an address of source (control terminal), reference numeral 302 an address of destination (remote controlled terminal), reference numeral 303 a type code of message (data), reference numeral 304 a key code representing the kind of input key, and reference numeral 305 a key flag indicating whether a key has been pressed or released.

The data input from the mouse 3B of the control terminal 100B is transmitted to the remote controlled

terminal 100A in a message format, for example, as shown in FIG. 5.

The message for mouse input data comprises a source address 301, a destination address 302, a message type code 303, a button operation flag 324 indicating a mouse movement or a mouse button operation such as press or release of a mouse button, an X coordinate 325 and a Y coordinate 326 of a mouse-controlled pointer (cursor).

10 Referring to FIG. 6, there is shown an operation in execution of the application program 11A on the remote controlled terminal 100A.

When the application program 11A is executed in response to remote operation input data, the results of execution are reflected on the display 2A. In this case, screen drawing data 40 for altering the displayed contents is output from the application program 11A to the display driver 12A through the operating system 10A and the display driver hooking controller 22A.

15

20 Thus, the current contents displayed on the display 2A are changed.

The display driver hooking controller 22A captures or copies the screen drawing data 40 transferred from the operating system 10A to the display driver 12A, and passes the screen drawing data 40 to

25

the remote operation basic controller 20A. Then, the screen drawing data 40 is converted into a predetermined-format message 41 by the remote operation basic controller 20A, and the message 41 is transmitted to the communication network 200 via the communication controller 26A.

The above message 41 is received by the communication controller 26B of the control terminal 100B and passed to the remote operation basic controller 20B. Then, the remote operation basic controller 20B extracts the screen drawing data 40 from the received message 41 and passes the screen drawing data 40 thus extracted to the display controller 27B. The display controller 27B outputs the screen drawing data 40 to the display driver 12B through the operating system 10B. Thus, the same contents as those on the remote controlled terminal 100A are presented on the display 2B of the control terminal 100B.

In the display driver hooking controller 22A of the remote controlled terminal 100A, there may be provided such an arrangement that the entire screen drawing data corresponding to the full window is captured at the start of remote operation and after that, partial screen drawing data corresponding to just a change portion (difference data) in the displayed

contents may be captured for reducing the amount of data to be transmitted, thereby to make a prompt response to the display 2B of the control terminal 100B even in the use of a communication line having a relatively low transmission rate.

Referring to FIG. 7, there is shown an example of a message format for sending screen drawing data from the remote controlled terminal 100A to the control terminal 100B.

As shown in FIG. 7, the message format for screen drawing data comprises a source address 301, a destination address 302, a message type code 303, an X coordinate 414 and a Y coordinate 415 indicating the origin of a screen drawing area, a width value 416 and a height value 417 indicating the width and height of the screen drawing area, a bitmap X coordinate 418 and a bitmap Y coordinate 419 indicating the start point of bitmap drawing, and bitmap data 420, for example.

Then, with reference to FIG. 8, the following describes a method of operation history recording to be performed at the remote controlled terminal 100A.

A change in the control state (startup, termination, etc.) of the application program 11A under the operating system 10A is captured by the application hooking controller 21A, and a change in the displayed

contents is captured by the display driver hooking controller 22A. Upon receipt of captured information from each of these hooking controllers, the remote operation basic controller 20A notifies the operation recording and playing controller 25A of an event source, event information and the current clock time to be stored as an operation history record. The remote operation basic controller 20A carries out the same processing on the remote operation input data, such as keyboard input data and mouse input data, received through the communication controller 26A, and notifies the remote operation recording and playing controller 25A of an event source, event information, and the current clock time.

Receiving the notification regarding the event source, event information and current clock time (time of event occurrence) from the remote operation basic controller 20A, the operation recording and playing controller 25A records them in a remote operation history file formed in the disk controller 5A. The location of a directory or a folder in which the remote operation history file is created can be specified for each remote operation, and operation history data may be encrypted as required.

Referring to FIG. 9, there is shown an example

of a remote operation history (remote control history) file 50. The remote operation history file 50 comprises a plurality of entries 50-1 to 50-6 created in the order of a time of event occurrence, and each entry includes the fields of: a time of event (time of event occurrence) 51, a source of event 52, contents of event 53, details of event 54, an object application 55, and a terminal name 56.

In the source-of-event field 52, the name of a hooking controller in which an event has occurred is recorded, for example, in such a manner as "keyboard", "mouse", "display" or "application". The contents-of-event field 53 holds data indicating what event has occurred; e.g., "left click" for the mouse, "Ctrl key input" for the keyboard, "bitmap drawing" or "character drawing" for the display, and "start" or "stop" for the application.

In the details-of-event field 54, bitmap information drawn is recorded when the source of event is "display" and the contents of event is "bitmap drawing", and the name of an application program started is recorded when the source of event is "application" and the contents of event is "start", for example. The object application field 55 holds the name of an application program subjected to an event input or

output, and the terminal name field 56 holds the name of a control terminal which has conducted remote operation. In a situation where an event has occurred in the remote controlled terminal of interest, the
5 terminal name field 56 is left blank.

The operation history data exemplified in FIG. 9 provides the following meanings: At 10:30:25, a left-click mouse input occurred in a file manager on terminal-A (50-1). At 10:30:26, word processor
10 software was started on the remote controlled terminal (50-2), and a window of the word processor was displayed (50-3). At 10:31:10, "test" was input to the word processor through a keyboard of terminal-A (50-4), and the "test" was displayed in the window of the word
15 processor on the remote controlled terminal (50-5). Then, at 10:40:30, the remote controlled terminal is disconnected from terminal A (50-6).

Referring to FIG. 10, a flowchart is shown to indicate the function of the operation recording and
20 playing controller 25A.

First, in the operation recording and playing controller (control routine) 25A, a process 100 for judgment on conditions of recording start is carried out. In this process 100, if an event group satisfying
25 start-of-recording conditions is recognized, a

parameter initialization process 120 is carried out to initialize parameters for judgment on termination of recording. Then, a wait is taken for an event input from the remote operation basic controller 20A (step
 5 125).

When an event is input, a process 130 for judgment on conditions of recording termination is carried out. In this process 130, if it is judged that termination-of-recording conditions are satisfied,
 10 control is returned to the process 100 for judgment on conditions of recording start to make preparation for recording the next remote operation history data. If it is judged that the termination-of-recording conditions are not satisfied, a process 140 for event
 15 recording is carried out and after that, control is returned to step 125 for waiting for the next event input.

Referring to FIGs. 11A to 11D, there are shown exemplary recording start events tables 60A to 60D for
 20 the used of defining start-of-recording conditions to be referenced in the process 100 for judgment on conditions of recording start.

The recording of remote operation history data is started on occurrence of a particular event specified
 25 in the recording start events table. Where

start-of-recording conditions are defined by a plurality of events in the recording start events table, it is judged that the start-of-recording conditions are satisfied if the plural events concerned occur in a predetermined sequence. Where a plurality of recording start events tables are prepared for indicating start-of-recording conditions, the recording of remote operation history data is started if start-of-recording conditions are satisfied in any of the recording start events tables.

In the recording start events table 60A shown in FIG. 11A, five events indicated by entries 60A-1 to 60A-5 are defined as start-of-recording conditions. Each entry includes the fields of: an event number 61 for specifying a sequence of occurrences of events, a source of event 62, contents of event 63, an object application 64, and a terminal name 65.

In the contents-of-event field 63, each event is defined in detail; e.g., "left click" for the mouse, "Ctrl key input" for the keyboard, and "start" or "control terminal connection" for the application, for example. The object application field 64 specifies the name of an application program subjected to an event input. The terminal name field 65 designates the name of a particular control terminal in a case where remote

operation by the particular control terminal is to be monitored. Where a control terminal is not specified or the event concerned is not associated with remote operation, the terminal name field 65 is left blank.

- 5 The recording start events table 60A provides the following definitions: The control terminal-A sets up a connection to the remote controlled terminal (60A-1), "Ctrl + Alt + Del" is input from the keyboard of the control terminal-A (60A-2), a "file manager" application program is started (60A-3), a "shared file" property window or dialogue is displayed by the "file manager" (60A-4), and after a lapse of five seconds (60A-5), the recording of remote operation history data is started. Although a plurality of events are defined
- 10 in the above table 60A, just a single event may be defined as a start-of-recording condition in a modified embodiment.

- The recording start events tables 60B, 60C and 60D are presented in FIGs. 11B to 11D as other exemplary
- 20 tables for defining start-of-recording conditions. In the table 60B, it is defined that after the control terminal-A sets up a connection to the remote controlled terminal, the "file manger" application program is started. In the table 60C, it is defined that after
- 25 the control terminal-A sets up a connection to the

remote controlled terminal, "word processor" software is started. In the table 60D, it is defined that after logging-on by user-B, "spreadsheet" software is started. Where a plurality of recording start events
 5 tables are provided as mentioned above, the recording of remote operation history data is started if start-of-recording conditions are satisfied in any of the recording start events tables.

Referring to FIGs. 12A to 12D, there are shown
 10 exemplary recording termination events tables 70A to 70D for the use of defining termination-of-recording conditions for remote operation history data to be referenced in the process 130 for judgment on conditions of recording termination.

15 In the recording termination events tables 70A to 70D, termination-of-recording conditions are defined by one or plural entries for specifying respective events. As in the recording start events tables 60A to 60D described above, each entry in the
 20 tables 70A to 70D includes the following fields: an event number 71, a source of event 72, contents of event 73, an object application 74, and a terminal name 75.

For example, in the recording termination events table 70A, it is defined as termination-of-recording
 25 conditions that a "file manager" application program

is terminated (70-A), "Ctrl + Alt + Del" is input from the keyboard of the control terminal A (70A-2), and then the control terminal A is disconnected (70A-3). In the recording termination events tables 70B, 70C
 5 and 70D, termination of the "file manager", "logging-off", and a lapse of "five minutes from start of recording" are defined as termination-of-recording conditions, respectively.

Where a plurality of recording termination events
 10 tables are prepared as mentioned above, the recording of remote operation history data is terminated on occurrence of an event which meets the termination-of-recording conditions defined in any of the recording termination events tables.

15 In the process 100 for judgment on conditions of recording start, a table counter 81 and an event counter 82 shown in FIG. 13 are used. Where a plurality of recording start events tables 60 are prepared as shown in FIGs. 11A to 11D, the table counter 81 indicates
 20 a value of parameter TC for identifying a table to be checked. The event counter 82 comprises a plurality of counter regions 82-1 to 82-n corresponding to the recording start events tables 60, each indicating a value of parameter EC for specifying an entry to be
 25 checked in each recording start events table.

In the following description, a recording start events table specified by the parameter TC is referred to a table TC, an event counter value for the table TC is referred to as EC[TC], and an event defined in the "EC"th entry in the table TC is referred to as a table event EC[TC].

Referring to FIG. 14, there are shown details of the process 100 for judgment on conditions of recording start.

10 In the process 100 for judgment on conditions of recording start, all the recording start events tables are read in (step 101), and the value of a parameter EC indicated by each event counter 82 is initialized (102). Then, the value of a parameter TC indicated by the table counter 81 is initialized (103), and a wait is taken for an event input from the remote operation basic controller 20A (104). When an event is input, the event (hereinafter referred to as the generated event) is compared with the corresponding
15 table event EC[TC] (105).

If the generated event does not match the table event EC[TC], the event counter value EC[TC] is initialized (106) and the table counter value TC is incremented (107). Then, it is judged whether or not
20 the table counter value TC exceeds the maximum number

of recording start events tables (108). If the table counter value TC exceeds the maximum number of recording start events tables, control is returned to step 103, whereby the table counter value TC is initialized and
 5 then a wait is taken for the next event. If the table counter value TC does not exceed the maximum number of recording start events tables, control is returned to step 105 in order to compare the generated event with the next table event EC[TC].

- 10 If the generated event matches the table event EC[TC], the event counter value EC[TC] is incremented (109) and then the incremented event counter value EC[TC] is compared with the maximum number "max[TC]" of entries in the table TC (110). If the incremented
 15 event counter value EC[TC] exceeds the max[TC], it signifies that start-of-recording conditions defined in the table TC are satisfied. The process 100 for judgment on conditions of recording start is therefore terminated. If the incremented event counter value
 20 EC[TC] does not exceed the max[TC], steps 107 and subsequent are repeated.

In the process 130 for judgment on conditions of recording termination, which will be described later, it is also required a parameter for identifying a
 25 recording termination events table 70 to be checked

and a parameter for specifying an entry to be checked in each recording termination events table. Since the process 130 for judgment on conditions of recording termination is carried out after completion of the process 100 for judgment on conditions of recording start, the table counter 81 and the event counter 82 can be used to indicate values of these parameters.

Referring to FIG. 15, there are shown details of the parameter initialization process 120 to be performed to initialize parameters for judgment on termination of recording. In this initialization process 120, all the recording termination events tables 70 are read in (step 121), and then the value of a parameter EC indicated by each event counter 82 is initialized (122).

Referring to FIG. 16, there are shown details of the process 130 for judgment on conditions of recording termination. In the description of this process 130, a recording termination events table specified by the parameter TC is referred to as a table TC, an event counter value for the table TC is referred to as EC[TC], and an event defined in the "EC"th entry in the table TC is referred to as a table event EC[TC].

In the process 130 for judgment on conditions of recording termination, the value of a parameter TC

indicated by the table counter 81 is initialized (step 131), and then a generated event is compared with the corresponding table event EC[TC] (132).

If the generated event does not match the table
5 event EC[TC], the event counter value EC[TC] is initialized (133) and the table counter value TC is incremented (134). Then, it is judged whether or not the table counter value TC exceeds the maximum number of recording termination events tables (135).

10 If the table counter value TC exceeds the maximum number of recording termination events tables, it signifies that all the events tables have been checked. The process 130 for judgment on conditions of recording termination is therefore terminated, and then the event
15 recording process 140 is carried out. If the table counter value TC does not exceed the maximum number of recording termination events tables, control is returned to step 132 in order to compare the generated event with the next table event EC[TC].

20 If the generated event matches the table event EC[TC], the event counter value EC[TC] is incremented (136) and then the incremented event counter value EC[TC] is compared with the maximum number "max[TC]" of entries in the table TC (137). If the incremented
25 event counter value EC[TC] exceeds the max[TC], it

signifies that termination-of-recording conditions defined in the table TC are satisfied. The process 130 for judgment on conditions of recording termination is therefore terminated, and control is returned to the process 100 for judgment on conditions of recording start shown in FIG. 10. If the incremented event counter value EC[TC] does not exceed the max[TC], steps 134 and subsequent are repeated.

Referring to FIG. 17, there are shown details of the event recording process 140.

In the event recording process 140, a source of each event is checked (step 141). If a keyboard event is received, a keyboard event recording step is carried out (142). If a mouse event is received, a mouse event recording step is carried out (143). If a display event is received, a display event recording step is carried out (144). If an application event is received, an application event recording step is carried out (145).

By the keyboard event recording step (142) noted above, for example, the entry 50-4 shown in FIG. 9 is recorded. By the mouse event recording step (143), the entry 50-1 is recorded. By the display event recording step (144), the entries 50-3 and 50-5 are recorded. By the application event recording step (145), the entries 50-2 and 50-6 are recorded.

Next, the following describes a procedure of playing control for reading out operation history data from the remote operation history file 50 in the disk controller 5A.

5 Referring to FIG. 18, there is shown a flow of operation history data in playing control at the remote controlled terminal 100A. The operation recording and playing controller 25A retrieves recorded operation history data from the remote operation history file
10 50 in the disk controller 5A and supplies the recorded operation history data to the remote operation basic controller 20A. Then, the remote operation basic controller 20A outputs the recorded operation history data to the display 2A through the operating system
15 10A and the display driver 12A.

Referring to FIG. 19, there is shown a flowchart of a playing control routine 150 in the operation recording and playing controller 25A.

In execution of the playing control routine 150,
20 a playing command from the user is waited (step 151). Upon reception of a read command issued by an enter key action for example, a count parameter "i" (initial value = 0) is incremented and the "i"th recorded event (entry 50-i) is read out from the remote operation
25 history file 50 (step 152). When there remains no

recorded event to be read out, a message indicating the end of playing control is presented (154) and the playing control routine 150 is terminated.

For the recorded event read out from the remote operation history file 50, the event source is checked to assign the event to a processing step corresponding to the event source (155). If a keyboard event is read out, a keyboard event playing step is carried out (156). If a mouse event is read out, a mouse event playing step is carried out (157). If a display event is read out, a display event playing step is carried out (158). If an application event is read out, an application event step is carried out (159). Upon completion of the playing step for one event, control is returned to step 151 to wait for the next read command.

In the remote operation history data shown in FIG. 9, events of interest to the user who is watching the display screen are, for example, the display events 50-3 and 50-5. These events are processed through the display event playing step (158). When the display event 50-3 is read out, a window of the word processor software is displayed. Then, when the display event 50-5 is read out, a character string "test" is presented on the window of the word processor.

The display event 50-3 has been generated through

execution of the mouse event 50-1 and execution of the application event 50-2 associated with the execution of the mouse event. The display event 50-5 has been generated through execution of the keyboard event 50-4.

- 5 In playing control, it is not required to execute each event actually in the keyboard event playing step (156) for processing the keyboard event 50-4, in the mouse event playing step (157) for processing the mouse event 50-1, and in the application playing step (159) for
10 processing the application event 50-2.

- Therefore, for example, it is preferable to provide such an arrangement that data items 51 to 56 contained in each event (entry 50-i) read out from the remote operation history file 50 are converted into
15 character strings in a predetermined format and these character strings are displayed to let the user know the details of remote operation and the state transitions of each application program. Further, in a modified arrangement, particular input operations,
20 e.g., only the mouse-related events, selected among from the operation history data may be played back in accordance with the designation by the user.

- Referring to FIG. 20, there is shown an example of a graphical user interface (GUI) window 90 to be
25 used for playing control of remote operation history

data.

In the GUI window 90 exemplified in FIG. 20, a file name 91 and a recording time 92 of each remote operation history file 50 are displayed. It is allowed
 5 for the user to specify a desired file to be played using a selection button 93 and a desired event type using one of a plurality of selection buttons 94 to 96. After specifying the desired file and event type using these selection buttons, the user clicks a play
 10 button 97. Thus, the playing control routine described above is started. Upon completion of execution of the playing control routine 150, if it is desired to play operation history data of another history file, the user repeats the procedure similar
 15 to that stated above. Alternatively, if it is desired to quit the playing of operation history data, the user may click a cancel button 98.

While the remote operation history recording function of the remote controlled terminal 100A has
 20 be described so far, the control terminal 100B can record the operation history data using the operation recording and playing controller 25B in a manner similar to that in conventional arrangements. If operation history data meeting each user need is accumulated at
 25 both the control terminal and the remote controlled

terminal, it is possible to reduce the amount of operation history data to be stored in the disk controller of each terminal. For example, the disk controller 5B of the control terminal may store the
5 history data as to input operations on the screen for an application program under the remote control while the disk controller 5A of the remote controlled terminal stores operation history data as to the entire desktop screen.

10 Although the recording of remote operation history data is automatically started when predetermined start-of-recording conditions are satisfied and the recording is automatically stopped when
15 predetermined termination-of-recording conditions are satisfied in the preferred embodiments described above, a recording pause period may be provided as required for reducing the amount of operation history data to be stored, i.e., history data recording may be carried out intermittently. In this
20 case, to compensate for discontinuity in screen transitions, it is preferable to capture the entire screen data each time history data recording is restarted on an intermittent basis.

According to the present invention, as set forth
25 hereinabove, since remote operation history data can

be stored at each remote controlled terminal, the user of the remote controlled terminal can easily check details of remote operation conducted by another person at the control terminal. Further, since remote
5 operation history data is distributively stored at a plurality of remote controlled terminals, it is possible to reduce the amount of remote operation history data to be stored at the control terminal.
